HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

COMPUTING VERSION SPACES IN THE QUALITATIVE APPROACH TO MULTICRITERIA DECISION AID

MIGUEL COUCEIRO, MIKLÓS MARÓTI, TAMÁS WALDHAUSER, AND LÁSZLÓ ZÁDORI

ABSTRACT. We consider a lattice-based model in multiattribute decision making, where preferences are represented by global utility functions that evaluate alternatives in a lattice structure (which can account for situations of indifference as well as of incomparability). Essentially, this evaluation is obtained by first encoding each of the attributes (nominal, qualitative, numeric, etc.) of each alternative into a distributive lattice, and then aggregating such values by lattice functions. We formulate version spaces within this model (global preferences consistent with empirical data) as solutions of an interpolation problem and present their complete descriptions accordingly. Moreover, we consider the computational complexity of this interpolation problem, and show that up to 3 attributes it is solvable in polynomial time, whereas it is NP complete over more than 3 attributes. Our results are then illustrated with a concrete example, namely, a recommender system for employees based on their psychological records throughout a year.

1. MOTIVATION

We consider a problem rooted in supervised learning and stated as an interpolation problem for functions $f: \mathbf{X} \rightarrow L$, where \mathbf{X} is a set of objects (or alternatives) and L is a set of labels: *Given a finite $S \subseteq \mathbf{X} \times L$, decide whether there exists an $f: \mathbf{X} \rightarrow L$ interpolating S , i.e., such that $f(\mathbf{a}) = b$ for every $(\mathbf{a}, b) \in S$.* Our motivation is found in the field of decision making, more specifically, in the qualitative approach to preference modeling and learning (prediction and elicitation).

As the starting point, we take the decomposable model to represent preferences over a set $\mathbf{X} = X_1 \times \cdots \times X_n$ of alternatives (e.g., houses to buy) described by n attributes $x_i \in X_i$ (e.g., price, size, location, color). In this setting, preference relations \preceq are represented by mappings $U: \mathbf{X} \rightarrow L$ valued in a scale L , and called “overall utility functions”, using the following rule:

$$\mathbf{x} \preceq \mathbf{y} \quad \text{if and only if} \quad U(\mathbf{x}) \leq U(\mathbf{y}).$$

This representation of preference relations is usually refined by taking into account “local preferences” \preceq_i on each X_i , modeled by mappings $\varphi_i: X_i \rightarrow L$ called “local utility functions”, which are then merged through an aggregation function $A: L^n \rightarrow L$ into an overall utility function U :

$$(1) \quad U(\mathbf{x}) = A(\varphi_1(x_1), \dots, \varphi_n(x_n)).$$

Loosely speaking, A merges the local preferences in order to obtain a global preference on the set of alternatives. In the qualitative setting, the aggregation function

Research supported by the Hungarian National Foundation for Scientific Research under grants no. K104251 and K115518, and by the János Bolyai Research Scholarship.

of choice is the *Sugeno integral* [25, 26] that can be regarded as an *idempotent lattice polynomial function* [6, 19], and the resulting global utility function (1) is then called a *pseudo-polynomial function* [10] or a *Sugeno utility function* [9] in the case when A is a Sugeno integral and the local utility functions are order-preserving. This observation brings the concept of Sugeno integral to domains more general than scales (linearly ordered sets) such as distributive lattices and Boolean algebras. Apart from the theoretic interest, such generalization is both natural and useful as it allows incomparability amongst alternatives, a situation that is most common in real-life situations. Preferences modelled by (1) were axiomatized by different approaches in [1, 4, 17].

The interest of considering the interpolation problem in this model-based setting becomes apparent when dealing with supervised learning of preference relations in the qualitative setting, and which leads naturally to the following extension of the interpolation problem: *Given a finite $S \subseteq \mathbf{X} \times L$, find all pseudo-polynomial functions $U: \mathbf{X} \rightarrow L$ that interpolate S .* In other words, given a data set S consisting of pairs (\mathbf{a}, b) of alternatives together with their evaluations, we would like to determine all models (1) that are consistent with S ; in the terminology of machine learning (see, e.g., [3, 20]) the set of all such models is called the *version space*.

A complete solution of the interpolation problem thus provides an explicit description of version spaces in the multicriteria setting. Solutions to particular instances have been presented in the literature. In particular, the problem of covering a set of data by a set of Sugeno integrals was considered in the linearly ordered case [22, 23] where conditions that guarantee the existence of a Sugeno integral interpolating a set of data were provided. Essentially, the set of interpolating Sugeno integrals (if they exist) was characterized as being upper and lower bounded by particular Sugeno integrals (easy to build from data). These results were then generalized in two different directions. In [21] an approach by “splines” was proposed, which enables elicitation of families of generalized Sugeno integrals from pieces of data where local and global evaluations may be imprecisely known, whereas in [5, 11] lattice theoretic approaches were proposed not only to determine existence but also to provide explicit descriptions of all possible lattice polynomials interpolating a given data set S .

In the current paper we solve the above mentioned pseudo-polynomial interpolation problem and thus describe version spaces for models (1). An important special case is the case of *quasi-polynomial functions* [7, 8], where $X_1 = \dots = X_n = X$ is an arbitrary set (not necessarily ordered) and $\varphi_1 = \dots = \varphi_n = \varphi: X \rightarrow L$. Such a framework is pertaining to *decision under uncertainty* and it is used to model situations where we need to take into account different states of a given world. For instance, X could stand for evaluations of well-being of individuals, such as

$$X = \{\text{excellent, physically down, mentally down, depressed}\},$$

in different periods, e.g., in $n = 4$ seasons so that each individual is represented by a tuple (x_1, x_2, x_3, x_4) whose components stand for her/his state in winter, spring, summer and autumn, respectively. Here, the goal could be a general evaluation of individuals providing a recommendation on the action to take, e.g.,

$$L = \{\text{continue job, continue job but look for alternatives, quit job}\}.$$

The paper is organized as follows. In Section 2 we recall basic notions and terminology in lattice theory, and present results and constructions pertaining to

interpolation by lattice polynomial functions. Extensions of the interpolation problem by pseudo- and quasi-polynomial functions are then proposed and solved in Section 3. For the sake of simplicity we present the solution in the setting of decision under uncertainty (interpolation by quasi-polynomials), but our method can be applied also in the multicriteria setting (interpolation by pseudo-polynomials). These results are then illustrated in Section 4 by a concrete example. In Section 5 we prove that for $n \geq 4$ it is an NP-complete problem to decide if the interpolation problem has a solution, while for $n \leq 3$ it can be decided in polynomial time. We conclude the paper in Section 6, where we indicate ongoing work and suggest other directions of future research.

Before proceeding, we would like to stress the fact that, despite motivated by a problem rooted in preference learning (see [13] for general background and a thorough treatment of the topic), our setting differs from the standard setting in machine learning. This is mainly due to the fact that we aim to describing utility-based preference models that are consistent with existing data (version spaces) rather than aiming to learning utility-based models by optimization (minimizing loss measures and coefficients) such as in, e.g., the probabilistic approach of [2] or the approach based on the Choquet integral of [27], and that naturally accounts for errors and inconsistencies in the learning data. Another difference is that, in the latter, data is supposed to be given in the form of feature vectors (thus assuming that local utilities over attributes are known a priori), an assumption that removes the additional difficulty that we face, namely, that of describing local utility functions that enable models based on the Sugeno integral that are consistent with existing data. It is also worth noting that we do not assume any structure on attributes and that we allow incomparabilities in evaluation spaces, which thus subsume preferences that are not necessarily rankings.

2. PRELIMINARIES

Throughout this paper let L be a distributive lattice. Recall that a *polynomial function over L* is a mapping $p: L^n \rightarrow L$ that can be expressed as a combination of the lattice operations \wedge and \vee , projections and constants. In the case when L is bounded, i.e., with a least and a greatest element, polynomial functions $p: L^n \rightarrow L$ can be represented in *disjunctive normal form* (DNF for short) by

$$(2) \quad p(\mathbf{y}) = \bigvee_{I \subseteq [n]} (c_I \wedge \bigwedge_{i \in I} y_i), \text{ where } \mathbf{y} = (y_1, \dots, y_n) \in L^n.$$

Here, and throughout the paper, we denote the set $\{1, 2, \dots, n\}$ by $[n]$. One can assume without loss of generality that the coefficients $c_I \in L$ are monotone in the sense that $c_I \leq c_J$ whenever $I \subseteq J$. Under this monotonicity assumption the coefficients of the DNF of the polynomial function p are uniquely determined.

As mentioned in Section 1, a natural model for supervised preference learning is the following interpolation problem, where a multivariable partial function on a lattice is to be interpolated by lattice polynomial functions.

Polynomial Interpolation Problem. Let L be a distributive lattice. Given an arbitrary finite set $D \subseteq L^n$ and $g: D \rightarrow L$, find all polynomial functions $p: L^n \rightarrow L$ such that $p|_D = g$.

Unlike in the case of interpolation by real polynomial functions, solutions do not necessarily exist, and it is a nontrivial problem to determine the necessary

FIGURE 1. A distributive lattice and its Boolean algebra

and sufficient conditions for the existence of an interpolating lattice polynomial function. Goodstein's theorem [15] provides a solution in the special case when the domain of g is the hypercube $D = \{0, 1\}^n$, where 0 and 1 are the least and greatest elements of the bounded distributive lattice L : a function $g: \{0, 1\}^n \rightarrow L$ can be interpolated by a polynomial function $p: L^n \rightarrow L$ if and only if g is monotone, and in this case p is unique. This result was generalized in [11] by allowing L to be an arbitrary (possibly unbounded) distributive lattice and by considering functions $g: D \rightarrow L$, where $D = \{a_1, b_1\} \times \cdots \times \{a_n, b_n\}$ with $a_i, b_i \in L$ and $a_i < b_i$, for each $i \in [n]$.

To describe the general solution of the Polynomial Interpolation Problem, which was given in [5], we need to recall that by the Birkhoff-Priestley representation theorem [12] we can embed any distributive lattice L into a Boolean algebra B , which can be assumed to be a subalgebra of the power set $\mathcal{P}(\Omega)$ of a set Ω . For the sake of canonicity, we assume that L generates B , so that B is uniquely determined up to isomorphism. The complement of an element $a \in B$ is denoted by a' . (See Figure 1 for an example.)

Given a function $g: D \rightarrow L$, we define the following two elements in B for each $I \subseteq [n]$:

$$c_I^- := \bigvee_{\mathbf{a} \in D} (g(\mathbf{a}) \wedge \bigwedge_{i \notin I} a'_i) \quad \text{and} \quad c_I^+ := \bigwedge_{\mathbf{a} \in D} (g(\mathbf{a}) \vee \bigvee_{i \in I} a'_i).$$

Observe that $I \subseteq J$ implies $c_I^- \leq c_J^-$ and $c_I^+ \leq c_J^+$. Let p^- and p^+ be the polynomial functions over B given by these two systems of coefficients:

$$p^-(\mathbf{y}) := \bigvee_{I \subseteq [n]} (c_I^- \wedge \bigwedge_{i \in I} y_i) \quad \text{and} \quad p^+(\mathbf{y}) := \bigvee_{I \subseteq [n]} (c_I^+ \wedge \bigwedge_{i \in I} y_i).$$

As it turns out [5], p^- and p^+ are the least and greatest polynomial functions over B whose restriction to D coincides with g (whenever such a polynomial function exists). This yields the following explicit description of all possible interpolating polynomial functions over the Boolean algebra B .

Theorem 1 ([5]). *Let L be a distributive lattice, and let B be the Boolean algebra generated by L . Let $g: D \rightarrow L$ be a function defined on a finite set $D \subseteq L^n$, and let $p: B^n \rightarrow B$ be a polynomial function over B given by (2). Then the following conditions are equivalent:*

- (i) p interpolates g , i.e., $p|_D = g$;
- (ii) $c_I^- \leq c_I \leq c_I^+$ for all $I \subseteq [n]$;
- (iii) $p^- \leq p \leq p^+$.

From Theorem 1 it follows that a necessary and sufficient condition for the existence of a polynomial function $p: B^n \rightarrow B$ such that $p|_D = g$ is $c_I^- \leq c_I^+$, for every $I \subseteq [n]$. Moreover, if for every $I \subseteq [n]$, there is $c_I \in L$ such that $c_I^- \leq c_I \leq c_I^+$, then and only then there is a polynomial function $p: L^n \rightarrow L$ such that $p|_D = g$. For the special type of interpolation problem considered in [11], the condition for the existence of a solution was given by simple lattice inequalities, without referring to the Boolean algebra generated by the lattice. In the case when L is a finite chain such a condition was given in [23], where, rather than polynomial functions, the interpolating functions were assumed to be Sugeno integrals, i.e., idempotent polynomial functions (see [18, 19]). One can also obtain the solution of the Polynomial Interpolation Problem over L in this case from Theorem 1 by describing explicitly the Boolean algebra generated by a finite chain. This yields the following result, which basically reformulates Theorem 3 in [23] in the language of lattice theory [5].

Theorem 2 ([23]). *Let L be a finite chain, and let $g: D \rightarrow L$ be a function defined on a subset $D \subseteq L^n$. Then there is a polynomial function $p: L^n \rightarrow L$ such that $p|_D = g$ if and only if*

$$(3) \quad \forall \mathbf{a}, \mathbf{b} \in D : g(\mathbf{a}) < g(\mathbf{b}) \implies \exists i \in [n] : a_i \leq g(\mathbf{a}) < g(\mathbf{b}) \leq b_i.$$

In contrast to the above mentioned special cases, in general it is not possible to avoid the use of the Boolean algebra generated by L , as it is illustrated by the following example.

Example 3 ([5]). Let L_5 be the five-element lattice shown in Figure 1a, and let $B(L_5)$ be the Boolean algebra generated by L_5 (see Figure 1b). Let $D = \{\mathbf{a}, \mathbf{b}\}$, where $\mathbf{a} = (1, c)$, $\mathbf{b} = (c, a)$ and consider $g: D \rightarrow L_5$ defined by

$$(4) \quad g(\mathbf{a}) = 1 \quad \text{and} \quad g(\mathbf{b}) = a.$$

As coefficients c_I^- and c_I^+ we obtain

$$\begin{aligned} c_\emptyset^- &= 0, & c_{\{1\}}^- &= c', & c_{\{2\}}^- &= 0, & c_{\{1,2\}}^- &= 1, \\ c_\emptyset^+ &= a, & c_{\{1\}}^+ &= b', & c_{\{2\}}^+ &= 1, & c_{\{1,2\}}^+ &= 1. \end{aligned}$$

We see that $c_I^- \leq c_I^+$ holds for each $I \subseteq [2]$, hence this interpolation problem has a solution over $B(L_5)$ (in fact, it has 32 solutions), by Theorem 1. On the other hand, no element of L_5 lies between $c_{\{1\}}^-$ and $c_{\{1\}}^+$, hence there is no solution over L_5 .

3. GENERALIZED LATTICE INTERPOLATION

As mentioned in the introduction, the motivation for considering the interpolation problem is rooted in the qualitative approach to preference modeling, where preference relations \preceq over a set $X_1 \times \cdots \times X_n$ of alternatives described by n attributes are represented by overall utility functions $U: X_1 \times \cdots \times X_n \rightarrow L$ valued in an ordered set L , by the rule:

$$\mathbf{x} \preceq \mathbf{y} \quad \text{if and only if} \quad U(\mathbf{x}) \leq U(\mathbf{y}).$$

Preferences on the attributes X_i are in turn modeled by local utility functions $\varphi_i: X_i \rightarrow L$, which are then aggregated through a lattice polynomial $p: L^n \rightarrow L$ thus giving rise to refined models

$$(5) \quad U(\mathbf{x}) = p(\varphi_1(x_1), \dots, \varphi_n(x_n)),$$

which we referred to as *pseudo-polynomial functions*.

The interest of considering the interpolation problem in this setting becomes apparent when dealing with preference relations that are partially defined. This situation of incomplete information pertains to preference learning, where the set of interpolating pseudo-polynomial functions constitutes its version space. This motivates the following extension of the interpolation problem (stated as Problem 5.1 in [11]):

Pseudo-polynomial Interpolation Problem. Let X_1, \dots, X_n be finite sets and L a finite distributive lattice. Given $C \subseteq X_1 \times \dots \times X_n$ and a partial function $f: C \rightarrow L$, find all pseudo-polynomial functions $U: X_1 \times \dots \times X_n \rightarrow L$ such that $U|_C = f$.

As mentioned in Section 1, uncertainty can be modeled by special kinds of pseudo-polynomials, where $X_1 = \dots = X_n = X$ and $\varphi_1 = \dots = \varphi_n = \varphi$. The resulting global utility functions $U: X^n \rightarrow L$ are so-called *quasi-polynomial functions*:

$$(6) \quad U(\mathbf{x}) = p(\varphi(x_1), \dots, \varphi(x_n)).$$

The corresponding interpolation problem can be formulated as follows:

Quasi-polynomial Interpolation Problem. Let X be a finite set and L a finite distributive lattice. Given $C \subseteq X^n$ and a partial function $f: C \rightarrow L$, find all quasi-polynomial functions $U: X^n \rightarrow L$ such that $U|_C = f$.

We present the solution of the Pseudo-polynomial Interpolation Problem in two steps. First, in Subsection 3.1 we show how to find the appropriate polynomials p provided that the local utility functions $\varphi_1, \dots, \varphi_n$ are given. Then, in Subsection 3.2 we give an algorithm to construct all possible local utility functions that could appear in an interpolation. To simplify the formalism, in Subsection 3.2 we consider the special case of quasi-polynomials, but our method can be easily adapted to the more general problem of pseudo-polynomial interpolation, see Remark 8.

3.1. Interpolation with known local utility functions. Assume that the local utility functions $\varphi_i: X_i \rightarrow L$ are given; our goal is to find all polynomial functions p over L such that the pseudo-polynomial function U given by (5) interpolates f . Let us consider an arbitrary polynomial function p over B in its disjunctive normal form (2). The corresponding pseudo-polynomial function $U = p(\varphi_1, \dots, \varphi_n)$ interpolates f if and only if $p(\varphi_1(a_1), \dots, \varphi_n(a_n)) = f(a_1, \dots, a_n)$ for all $\mathbf{a} \in C$, i.e., if p interpolates the function $g: D \rightarrow L$ defined on the set

$$D = \{(\varphi_1(a_1), \dots, \varphi_n(a_n)) : \mathbf{a} \in C\}$$

by

$$g(\varphi_1(a_1), \dots, \varphi_n(a_n)) = f(a_1, \dots, a_n).$$

Using the construction of Section 2 for this interpolation problem, we can define coefficients $c_{I,\varphi_1,\dots,\varphi_n}^-$ and $c_{I,\varphi_1,\dots,\varphi_n}^+$ for every $I \subseteq [n]$ as follows:

$$c_{I,\varphi_1,\dots,\varphi_n}^- := \bigvee_{\mathbf{a} \in C} (f(\mathbf{a}) \wedge \bigwedge_{i \notin I} \varphi_i(a_i)') \quad \text{and} \quad c_{I,\varphi_1,\dots,\varphi_n}^+ := \bigwedge_{\mathbf{a} \in C} (f(\mathbf{a}) \vee \bigvee_{i \in I} \varphi_i(a_i)').$$

Denoting the corresponding polynomial functions by $p_{\varphi_1,\dots,\varphi_n}^-$ and $p_{\varphi_1,\dots,\varphi_n}^+$, Theorem 1 yields the following solution for the Pseudo-polynomial Interpolation Problem with known local utility functions.

Theorem 4. *Let X_1, \dots, X_n be finite sets, let L be a finite distributive lattice, and let $f: C \rightarrow L$ be a function defined on a set $C \subseteq X_1 \times \dots \times X_n$. For any maps $\varphi_i: X_i \rightarrow L$ ($i \in [n]$) and any polynomial function $p: B^n \rightarrow B$ over B given by (2), the following conditions are equivalent:*

- (i) $U = p(\varphi_1, \dots, \varphi_n)$ interpolates f , i.e., $U|_C = f$;
- (ii) $c_{I,\varphi_1,\dots,\varphi_n}^- \leq c_I \leq c_{I,\varphi_1,\dots,\varphi_n}^+$ for all $I \subseteq [n]$;
- (iii) $p_{\varphi_1,\dots,\varphi_n}^- \leq p \leq p_{\varphi_1,\dots,\varphi_n}^+$.

Remark 5. Note that if there exist tuples $\mathbf{a}, \mathbf{b} \in C$ such that $f(\mathbf{a}) \neq f(\mathbf{b})$ but $(\varphi_1(a_1), \dots, \varphi_n(a_n)) = (\varphi_1(b_1), \dots, \varphi_n(b_n))$, then it is clearly impossible to find an interpolating pseudo-polynomial function (or any kind of function at all). We invite the reader to verify that this situation cannot occur if condition (ii) of Theorem 4 is satisfied.

3.2. Interpolation with unknown local utility functions. Now let us consider interpolation by quasi-polynomial functions

$$U(\mathbf{x}) = p(\varphi(x_1), \dots, \varphi(x_n)),$$

where the local utility function $\varphi: X \rightarrow L$ is not known. Our aim is to find all possible maps φ for which an interpolating polynomial exists. Specializing the results of the previous subsection to the case $\varphi_1 = \dots = \varphi_n = \varphi$, we see that the necessary and sufficient condition for the existence of a solution over B is that $c_{I,\varphi}^- \leq c_{I,\varphi}^+$ for all $I \subseteq [n]$, where

$$c_{I,\varphi}^- := \bigvee_{\mathbf{a} \in C} (f(\mathbf{a}) \wedge \bigwedge_{i \notin I} \varphi(a_i)') \quad \text{and} \quad c_{I,\varphi}^+ := \bigwedge_{\mathbf{a} \in C} (f(\mathbf{a}) \vee \bigvee_{i \in I} \varphi(a_i)').$$

Equivalently, we must have

$$(7) \quad \forall \mathbf{a}, \mathbf{b} \in C \quad \forall I \subseteq [n]: \quad f(\mathbf{a}) \wedge \bigwedge_{i \notin I} \varphi(a_i)' \leq f(\mathbf{b}) \vee \bigvee_{i \in I} \varphi(b_i)'. \quad \text{and} \quad c_{I,\varphi}^- \leq c_{I,\varphi}^+$$

Thus, we have a system of inequalities for the unknown values $\varphi(a)$ ($a \in X$). To find all solutions of this system of inequalities, we make use of the fact that B can be embedded into the power set of a set Ω . We will encode a map $\varphi: X \rightarrow B$ by a system of sets $S_\omega \subseteq X$ ($\omega \in \Omega$), where $S_\omega = \{a \in X: \omega \in \varphi(a)\}$. It is straightforward to verify that the inequalities (7) translate to the following condition for the sets S_ω :

$$(8) \quad \forall \omega \in f(\mathbf{a}) \setminus f(\mathbf{b}) \quad \forall I \subseteq [n]: \quad \{b_i: i \in I\} \subseteq S_\omega \implies \{a_i: i \notin I\} \cap S_\omega \neq \emptyset.$$

(Here $f(\mathbf{a}) \setminus f(\mathbf{b})$ is the difference of the sets $f(\mathbf{a}), f(\mathbf{b}) \subseteq \Omega$.)

Observe that for given $\omega \in \Omega$ and $\mathbf{a}, \mathbf{b} \in C$, it is sufficient to consider the set $I = \{i \in [n]: b_i \in S_\omega\}$ in (8) instead of all subsets of $[n]$, since this gives the strongest condition. Hence we may construct S_ω by starting with the empty set, and

Algorithm 1 Constructing all possible sets S_ω

```

1:  $S_\omega := \emptyset$ 
2: compute  $\mathcal{E}$  by (9)
3: repeat
4:   add a covering set of  $\mathcal{H} = (X, \mathcal{E})$  to  $S_\omega$ 
5:   recompute  $\mathcal{E}$  by (9)
6: until  $\mathcal{E} = \emptyset$  or  $\emptyset \in \mathcal{E}$ 
7: if  $\mathcal{E} = \emptyset$  then
8:   return  $S_\omega$ 
9: else
10:  return fail
11: end if

```

adding an element of $\{a_i : i \notin I\}$ if necessary, for all $\mathbf{a}, \mathbf{b} \in C$ with $\omega \in f(\mathbf{a}) \setminus f(\mathbf{b})$ and $I = \{i \in [n] : b_i \in S_\omega\}$. However, note that we must not add too many elements to S_ω , since if $\{b_i : i \in [n]\} \subseteq S_\omega$, then (8) yields the contradiction $\emptyset \cap S_\omega \neq \emptyset$.

At any stage of this process, let us collect all the sets $\{a_i : i \notin I\}$ of which we must add an element to S_ω :

$$(9) \quad \mathcal{E} := \left\{ \{a_i : i \notin I\} : \mathbf{a}, \mathbf{b} \in C, \omega \in f(\mathbf{a}) \setminus f(\mathbf{b}), \right. \\ \left. I = \{i \in [n] : b_i \in S_\omega\}, \{a_i : i \notin I\} \cap S_\omega = \emptyset \right\}.$$

This way we obtain a hypergraph $\mathcal{H} = (X, \mathcal{E})$, and condition (8) requires that a *vertex cover* (i.e., a set of vertices intersecting every hyperedge) of \mathcal{H} be included in S_ω . This yields Algorithm 1 for constructing S_ω .

The algorithm terminates when either $\mathcal{E} = \emptyset$, which means that (8) is satisfied, hence we do not need to add any more elements to S_ω , or $\emptyset \in \mathcal{E}$, which means that the above mentioned contradiction $\emptyset \cap S_\omega \neq \emptyset$ occurs, and it cannot be resolved by adding more elements to S_ω . In order to make sure that we find all possible solutions, we must try *every* covering set of \mathcal{H} in line 4 of the algorithm in every iteration. If we would like to find just one solution (if there is one at all), then it is sufficient to add a minimal covering set of \mathcal{H} , but still we must try *every* minimal covering set in every iteration, leading to an exponential running time.

Remark 6. The example of Section 4 shows that this cannot be avoided, since it is possible that certain covering sets may lead to a contradiction, while other covering sets give a solution. Also, in Section 5 we prove that even deciding the existence of an interpolating quasi-polynomial function is an NP-complete problem, hence an effective algorithm cannot be expected unless $P = NP$.

To determine the whole version space, i.e., the set of all interpolating quasi-polynomial functions, one needs to compute all possible systems of sets S_ω ($\omega \in \Omega$), and then one can define the corresponding local utility functions $\varphi : X \rightarrow B$ by $\varphi(a) = \{\omega \in \Omega : a \in S_\omega\}$. After computing all such maps φ , one can select those for which $\varphi(a) \in L$ holds for all $a \in X$. Then using the construction of Subsection 3.1 one can determine the corresponding polynomial functions p for each φ . Recall that the coefficients $c_{I,\varphi}^-, c_{I,\varphi}^+$ belong to B , but we need only the elements of L that lie between $c_{I,\varphi}^-$ and $c_{I,\varphi}^+$.

Example 7. Note that the current setting is strictly more general than that of the previous section. To illustrate this, let $X = \{0, a, 1\} = L$ and $C = \{(0, 1), (1, 0), (a, a), (1, 1)\}$. (The ordering on L is $0 < a < 1$, i.e., L is a three-element chain. Then B can be chosen as $\{0, a, a', 1\}$ with $0 < a, a' < 1$.) Consider $f: C \rightarrow L$ given by

$$\begin{aligned} f(a, a) &= 0, \\ f(0, 1) &= f(1, 0) = a, \\ f(1, 1) &= 1. \end{aligned}$$

Using Theorem 1, we can verify that there is no polynomial function that would interpolate f on C (even if considered over the Boolean lattice B extending L). However, taking $\varphi: X \rightarrow L$ given by $\varphi(0) = \varphi(a) = 0$ and $\varphi(1) = 1$, we get

$$\begin{aligned} c_{\emptyset, \varphi}^- &= c_{\emptyset, \varphi}^+ = 0, \\ c_{\{1\}, \varphi}^- &= c_{\{1\}, \varphi}^+ = c_{\{2\}, \varphi}^- = c_{\{2\}, \varphi}^+ = a, \\ c_{\{1, 2\}, \varphi}^- &= c_{\{1, 2\}, \varphi}^+ = 1. \end{aligned}$$

Hence, $p = p_{\varphi}^- = p_{\varphi}^+ = (a \wedge x_1) \vee (a \wedge x_2) \vee (1 \wedge x_1 \wedge x_2)$, and it is not difficult to verify that $U = p \circ \varphi$ indeed interpolates f .

Remark 8. Let $U: X_1 \times \cdots \times X_n \rightarrow L$ be a pseudo-polynomial function of the form (5). Assume (without loss of generality) that the sets X_1, \dots, X_n are pairwise disjoint, and let $X = X_1 \cup \cdots \cup X_n$ and $\varphi = \varphi_1 \cup \cdots \cup \varphi_n$. Consider the quasi-polynomial function $\tilde{U}: X^n \rightarrow L$ defined by $\tilde{U}(\mathbf{x}) = p(\varphi(x_1), \dots, \varphi(x_n))$. Observe that $X_1 \times \cdots \times X_n \subseteq X^n$ and the restriction of \tilde{U} to $X_1 \times \cdots \times X_n$ coincides with U . Thus, every pseudo-polynomial function can be viewed as a restriction of a quasi-polynomial function. Conversely, if $p(\varphi(x_1), \dots, \varphi(x_n))$ is a quasi-polynomial function over X , then its restriction to $X_1 \times \cdots \times X_n$ is a pseudo-polynomial function corresponding to the local utility functions $\varphi_i = \varphi|_{X_i}$ ($i = 1, \dots, n$). This observation allows us to use Algorithm 1 almost verbatim to solve the Pseudo-polynomial Interpolation Problem.

4. A CASE STUDY

We illustrate the construction of the version space outlined in the previous section on the example mentioned in Section 1. Our setup is the following:

- $L = \{0, a, 1\}$, where 0 means “quit job”, a means “continue job but look for alternatives” and 1 means “continue job”. We take the natural ordering $0 < a < 1$ on L .
- $X = \{E, P, M, D\}$, where E means “excellent”, P means “physically down”, M means “mentally down” and D means “depressed”. We do not need an order structure on X , however, it seems natural to consider E and D as the best and worst cases, and P and M lie between them: $D < P, M < E$.
- $C = \{(P, E, D, P), (E, D, P, P), (D, E, M, M), (P, M, E, D), (M, M, E, P)\}$, and $f: C \rightarrow L$ is given by

$$\begin{aligned} f(P, E, D, P) &= 0, & f(P, M, E, D) &= 1, \\ f(E, D, P, P) &= a, & f(M, M, E, P) &= 1, \\ f(D, E, M, M) &= a. \end{aligned}$$

The lattice L can be embedded into the power set of a two-element set $\Omega = \{\omega_1, \omega_2\}$, hence we have $B = \mathcal{P}(\Omega)$, and we regard the elements of L as subsets of Ω :

$$0 = \emptyset, \quad a = \{\omega_1\}, \quad 1 = \{\omega_1, \omega_2\}.$$

Note that $B = \{0, a, a', 1\}$, where $a' = \{\omega_2\}$. One can interpret ω_1 as “continue job” and ω_2 as “do not look for alternatives”. Then a' would mean “quit job but do not look for alternatives”, which is naturally excluded from the set of possible options.

Let us compute (some of) the possible sets S_{ω_1} that satisfy (8). Starting with $S_{\omega_1} = \emptyset$ we have $\mathcal{E} = \{\{E, P, M, D\}, \{E, M, D\}, \{E, P, D\}, \{E, P, M\}\}$ by (9). The hypergraph $\mathcal{H} = (X, \mathcal{E})$ has 4 minimal covering sets, namely $\{E\}, \{P, M\}, \{P, D\}, \{M, D\}$. Any subset of X containing one of these sets is a covering set; there are altogether 12 covering sets, and we should examine each one of them in order to find all solutions. This is rather tedious, hence we give the details only for the minimal covering sets.

Setting $S_{\omega_1} = \{E\}$, we obtain $\mathcal{E} = \{\{M, D\}\}$, hence we must add either M or D to S_{ω_1} . In the former case we get $\mathcal{E} = \emptyset$, which yields the solution $S_{\omega_1} = \{E, M\}$. In the latter case we have $S_{\omega_1} = \{E, D\}$ and $\mathcal{E} = \{\{P, M\}\}$, hence one of P and M must be added to S_{ω_1} . The case $S_{\omega_1} = \{E, P, D\}$ gives $\mathcal{E} = \{\emptyset\}$, and the corresponding hypergraph has no covering sets. The case $S_{\omega_1} = \{E, M, D\}$ gives $\mathcal{E} = \emptyset$, and this means that there are no edges that need to be covered, i.e., $S_{\omega_1} = \{E, M, D\}$ satisfies (8). The rest of the computation is shown on Figure 2. Note that if we had started with $S_{\omega_1} = \{P, D\}$ instead of $S_{\omega_1} = \{E\}$ at the beginning, then we would have gotten no solutions. This illustrates that one must search the whole tree of possibilities in order to guarantee that a solution will be found if there is one.

Figure 3 shows the computations for S_{ω_2} , again only working with minimal covering sets. Taking into account non-minimal covering sets as well, one obtains all possible sets S_{ω_1} and S_{ω_2} :

$$\begin{aligned} S_{\omega_1} : & \{E, M\}, \{P, M\}, \{M, D\}, \{E, P, M\}, \{E, M, D\}; \\ S_{\omega_2} : & \{E\}, \{M\}, \{P, M\}, \{M, D\}, \{E, P, M\}, \{P, M, D\}. \end{aligned}$$

There are 30 possibilities for the systems of sets S_{ω} ($\omega \in \Omega$), hence there are 30 maps $\varphi: X \rightarrow B$ for which an interpolating polynomial exists over B . However, if there is an element $u \in S_{\omega_2} \setminus S_{\omega_1}$, then $\varphi(u) = a' \notin L$. Therefore, it suffices to consider the cases where $S_{\omega_2} \subseteq S_{\omega_1}$, giving 13 local utility functions $\varphi: X \rightarrow L$.

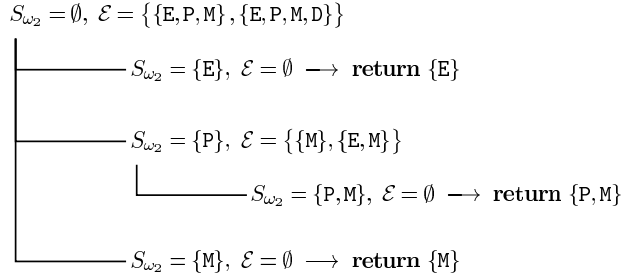

If we consider the partial ordering $D < P, M < E$ on X and we look only for order-preserving maps φ , then we have only 3 possibilities. We give the corresponding polynomial functions p_{φ}^- and p_{φ}^+ only for these cases (for easier readability we omit the \wedge signs and write meets simply as juxtapositions):

- $S_{\omega_1} = \{E, P, M\}, S_{\omega_2} = \{E, P, M\}$: In this case we have

$$\begin{aligned} \varphi(E) = 1, \quad \varphi(P) = 1, \quad \varphi(M) = 1, \quad \varphi(D) = 0; \\ p_{\varphi}^- = y_1 y_2 y_3 \vee a y_1 y_3 y_4 \vee a y_2 y_3 y_4, \quad p_{\varphi}^+ = a y_3 \vee y_1 y_2 y_3. \end{aligned}$$

- $S_{\omega_1} = \{E, M\}, S_{\omega_2} = \{E\}$: In this case we have

$$\begin{aligned} \varphi(E) = 1, \quad \varphi(P) = 0, \quad \varphi(M) = a, \quad \varphi(D) = 0; \\ p_{\varphi}^- = a y_1 \vee a' y_3 \vee y_1 y_3 \vee y_2 y_3, \quad p_{\varphi}^+ = a y_1 \vee y_3 \vee y_4 \vee y_1 y_2. \end{aligned}$$

FIGURE 2. Computing S_{ω_1} FIGURE 3. Computing S_{ω_2}

Here p_{φ}^{-} involves a' as a coefficient, hence it is not a polynomial over L . The least polynomial p over L satisfying $p_{\varphi}^{-} \leq p$ is obtained by replacing a' by 1:

$$p = ay_1 \vee 1y_3 \vee y_1y_3 \vee y_2y_3 = ay_1 \vee y_3.$$

Probably this is the simplest polynomial over L that lies between p_{φ}^{-} and p_{φ}^{+} ; the corresponding quasi-polynomial $U(\mathbf{x}) = a\varphi(x_1) \vee \varphi(x_3)$ depends only on x_1 and x_3 , which shows that it suffices to evaluate the person's well-being in winter and summer in order to choose the action to take.

- $S_{\omega_1} = \{E, P, M\}, S_{\omega_2} = \{E\}$: In this case we have

$$\varphi(E) = 1, \varphi(P) = a, \varphi(M) = a, \varphi(D) = 0;$$

$$p_{\varphi}^{-} = a'y_3 \vee y_1y_2y_3 \vee y_1y_3y_4 \vee y_2y_3y_4, \quad p_{\varphi}^{+} = y_3 \vee a'y_4 \vee a'y_1y_2.$$

Again a' appears in the polynomials; we need to replace it by 1 in p_φ^- and by 0 in p_φ^+ to all find polynomials p over L such that $p_\varphi^- \leq p \leq p_\varphi^+$. After simplification, we get the polynomial y_3 in both cases. This means that for this local utility function the interpolating quasi-polynomial is unique: $U(\mathbf{x}) = \varphi(x_3)$; revealing the fact that x_3 (i.e., the person's well-being in summer) alone can determine the recommended action to take.

5. COMPLEXITY OF QUASI-POLYNOMIAL INTERPOLATION

In Section 3 we gave an algorithm that constructs all quasi-polynomial functions interpolating a given partial function $f: C \rightarrow L$ ($C \subseteq X^n$). We noticed that even if one looks for only one interpolating quasi-polynomial, the algorithm still involves finding minimal covering sets in hypergraphs, which is an NP-complete problem [14]. In this section we prove that this difficulty is not avoidable, as already for $n = 4$, it is an NP-complete problem to decide whether an interpolating quasi-polynomial exists. However, as we shall see, for $n \leq 3$ this problem can be solved in polynomial time. For background on complexity theory we refer the reader to [14].

First let us observe that it is sufficient to consider the case where L is the two-element lattice. Indeed, if L is any finite distributive lattice, then, as before, we embed L into a power set $\mathcal{P}(\Omega)$ of a finite set Ω , and consider the elements $\omega \in \Omega$ separately, as we did in (8). In this way we can translate the Quasi-polynomial Interpolation Problem to $|\Omega|$ many problems with two-element lattices $\mathcal{P}(\{\omega\})$. Therefore, in the sequel we will always assume that $L = \{0, 1\}$.

We will examine the complexity of our interpolation problem with the help of certain constraint satisfaction problems that are related to upsets in the Boolean lattice $L^n = \{0, 1\}^n$. We say that a subset $\alpha \subseteq L^n$ is an *upset* (order filter) if $\mathbf{a}_1 \in \alpha$ and $\mathbf{a}_1 \leq \mathbf{a}_2$ (in the componentwise ordering) imply $\mathbf{a}_2 \in \alpha$ for all $\mathbf{a}_1, \mathbf{a}_2 \in L^n$. We will denote the complement of α by β , i.e., $\beta = L^n \setminus \alpha$. Observe that β is a *downset* (order ideal): $\mathbf{b}_1 \in \beta$ and $\mathbf{b}_1 \geq \mathbf{b}_2$ imply $\mathbf{b}_2 \in \beta$ for all $\mathbf{b}_1, \mathbf{b}_2 \in L^n$. For every upset $\alpha \subseteq L^n$ we define a problem $\mathbf{P}(\alpha)$ as follows.

Problem $\mathbf{P}(\alpha)$. Given a finite set V of variables and sets of n -tuples $A, B \subseteq V^n$, find an assignment $\psi: V \rightarrow L$ such that $\psi(\mathbf{a}) \in \alpha$ for all $\mathbf{a} \in A$ and $\psi(\mathbf{b}) \in \beta = L^n \setminus \alpha$ for all $\mathbf{b} \in B$.

Note that $\mathbf{P}(\alpha)$ is a Boolean constraint satisfaction problem, hence, by Schaefer's dichotomy theorem for Boolean CSP, it is either in P or NP-complete [24].

Lemma 9. *Let $L = \{0, 1\}$ be the two-element lattice, let X be a finite set and $f: C \rightarrow L$ ($C \subseteq X^n$). There exists a quasi-polynomial function interpolating f if and only if $\mathbf{P}(\alpha)$ has a solution for some upset $\alpha \subseteq L^n$ with $V = X$ and*

$$A = \{\mathbf{a} \in C: f(\mathbf{a}) = 1\}, \quad B = \{\mathbf{b} \in C: f(\mathbf{b}) = 0\}.$$

Proof. As we have seen in Section 3, an interpolating quasi-polynomial exists if and only if there is a map $\varphi: X \rightarrow L$ satisfying (7). If $f(\mathbf{a}) = 0$ or $f(\mathbf{b}) = 1$, then the inequality of (7) clearly holds for all $I \subseteq [n]$. For $f(\mathbf{a}) = 1$ and $f(\mathbf{b}) = 0$, the inequality holds for all $I \subseteq [n]$ if and only if there is an index $i \in [n]$ such that $\varphi(a_i) = 1$ and $\varphi(b_i) = 0$, i.e., $\varphi(\mathbf{a}) \not\leq \varphi(\mathbf{b})$ in the componentwise ordering of n -tuples over $L = \{0, 1\}$. Thus, (7) is equivalent to the following condition:

$$(10) \quad \forall \mathbf{a}, \mathbf{b} \in C: (f(\mathbf{a}) = 1 \text{ and } f(\mathbf{b}) = 0) \implies \varphi(\mathbf{a}) \not\leq \varphi(\mathbf{b}).$$

(Note that the implication in (10) can be reformulated as $\varphi(\mathbf{a}) \leq \varphi(\mathbf{b}) \implies f(\mathbf{a}) \leq f(\mathbf{b})$. This gives an alternative way of proving that (10) is equivalent to the existence of a polynomial p such that $f(\mathbf{c}) = p(\varphi(\mathbf{c}))$ for all $\mathbf{c} \in C$, since lattice polynomial functions coincide with nondecreasing functions over the two-element lattice.)

Assume that φ satisfies (10), and let α be the least upset containing $\varphi(\mathbf{a})$ for all $\mathbf{a} \in A$:

$$\alpha := \{\mathbf{y} \in L^n : \mathbf{y} \geq \varphi(\mathbf{a}) \text{ for some } \mathbf{a} \in A\}.$$

Obviously, we have $\varphi(\mathbf{a}) \in \alpha$ for all $\mathbf{a} \in A$, and (10) implies that $\varphi(\mathbf{b}) \notin \alpha$ for all $\mathbf{b} \in B$. Thus, φ is a solution of the problem $\mathbf{P}(\alpha)$ with X being the set of variables.

Conversely, if $\alpha \subseteq L^n$ is an arbitrary upset and φ is a solution of $\mathbf{P}(\alpha)$, then it is immediate that φ satisfies (10). \square

According to Lemma 9, we can split the Quasi-polynomial Interpolation Problem into finitely many subproblems $\mathbf{P}(\alpha)$ with α running through the set of upsets of L^n . If each of these subproblems can be solved in polynomial time, then the whole problem is in P. As the next theorem shows, this is the case for $n \leq 3$.

Theorem 10. *If $n \leq 3$, then the problem of deciding the existence of an interpolating quasi-polynomial function belongs to the complexity class P.*

Proof. Clearly, it suffices to prove the theorem for $n = 3$. By Lemma 9, we only need to show that $\mathbf{P}(\alpha)$ is in P for every upset $\alpha \subseteq L^3$. Up to permutations of variables, we have the 8 cases listed below. For each upset α we give a polymorphism h of the constraint language $\{\alpha, \beta\}$ that shows that $\mathbf{P}(\alpha)$ belongs to P by Schaefer's dichotomy theorem. (For better readability we write elements of L^3 as words.)

$\alpha = \{111\}$	$h = x \wedge y$
$\alpha = \{101, 111\}$	$h = x \wedge y$
$\alpha = \{101, 110, 111\}$	$h = (x \wedge y) \vee (x \wedge z) \vee (y \wedge z)$
$\alpha = \{100, 101, 110, 111\}$	$h = x \wedge y$
$\alpha = \{011, 101, 110, 111\}$	$h = (x \wedge y) \vee (x \wedge z) \vee (y \wedge z)$
$\alpha = \{011, 100, 101, 110, 111\}$	$h = (x \wedge y) \vee (x \wedge z) \vee (y \wedge z)$
$\alpha = \{010, 011, 100, 101, 110, 111\}$	$h = x \vee y$
$\alpha = \{001, 010, 011, 100, 101, 110, 111\}$	$h = x \vee y$ \square

For $n \geq 4$ one can find upsets $\alpha \subseteq L^n$ such that $\mathbf{P}(\alpha)$ is NP-complete. This does not yield immediately NP-completeness of the interpolation problem, since there might be “easy” solutions corresponding to some other upsets. Nevertheless, in the next theorem we prove that the Quasi-polynomial Interpolation Problem is indeed NP-complete for $n \geq 4$.

Theorem 11. *If $n \geq 4$, then the problem of deciding the existence of an interpolating quasi-polynomial function is NP-complete.*

Proof. Clearly, it suffices to prove the theorem for $n = 4$. Let $\alpha \subseteq \{0, 1\}^4$ be the upset consisting of tuples of Hamming weight at least 3, that is, $\alpha := \{0111, 1011, 1101, 1110, 1111\}$. In this case the constraint language $\{\alpha, \beta\}$ admits only projections as polymorphisms, thus $\mathbf{P}(\alpha)$ is NP-complete, by Schaefer's dichotomy theorem.

For every instance of $\mathbf{P}(\alpha)$ we construct an instance of the quasi-polynomial interpolation problem with $L = \{0, 1\}$ and $n = 4$ such that the solutions ψ of the former are in a one-to-one correspondence with the local utility functions φ that solve the latter. So assume that V and $A, B \subseteq V^4$ are given, as in $\mathbf{P}(\alpha)$. Let $X = V \dot{\cup} \{0, 1\}$, $C = A \cup B \dot{\cup} \{0, 1\}^4$ (where $\dot{\cup}$ denotes disjoint union) and $f: C \rightarrow L^4$ such that

$$\forall \mathbf{a} \in A \cup \alpha: f(\mathbf{a}) = 1 \quad \text{and} \quad \forall \mathbf{b} \in B \cup \beta: f(\mathbf{b}) = 0.$$

(Note that 0 and 1 belong to both X and L , hence they play the role of “variables” as well as the role of “values”.) We claim that a map $\varphi: X \rightarrow L$ satisfies (10), which, as we have seen in Lemma 9, is equivalent to (7), if and only if $\varphi(0) = 0$ and $\varphi(1) = 1$, and the restriction $\psi := \varphi|_V$ of φ to V is a solution of $\mathbf{P}(\alpha)$.

First suppose that φ satisfies (10). This immediately implies that $\varphi(\mathbf{a}) \not\leq \varphi(\mathbf{b})$ for all $\mathbf{a} \in \alpha$ and $\mathbf{b} \in \beta$, and it is easy to see that this holds if and only if $\varphi(0) = 0$ and $\varphi(1) = 1$. Now applying (10) with $\mathbf{a} \in A$, $\mathbf{b} \in \beta$, we get $\varphi(\mathbf{a}) \not\leq \varphi(\mathbf{b}) = \mathbf{b}$; in particular, $\varphi(\mathbf{a}) \neq \mathbf{b}$. Since this holds for all $\mathbf{b} \in \beta$, we have that $\varphi(\mathbf{a}) \notin \beta$, i.e., $\varphi(\mathbf{a}) \in \alpha$. A similar argument shows that $\varphi(\mathbf{b}) \in \beta$ for all $\mathbf{b} \in B$, and this proves that $\psi = \varphi|_V$ is indeed a solution to $\mathbf{P}(\alpha)$.

Next assume that ψ is a solution of $\mathbf{P}(\alpha)$, and let $\varphi: X \rightarrow L$ coincide with ψ on V , and let $\varphi(0) = 0$, $\varphi(1) = 1$. Then we have $\varphi(\mathbf{a}) \in \alpha$ for all $\mathbf{a} \in A \cup \alpha$ (if $\mathbf{a} \in A$ then by the constraints of $\mathbf{P}(\alpha)$, if $\mathbf{a} \in \alpha$ then by the fact that $\varphi(\mathbf{a}) = \mathbf{a}$), and similarly, $\varphi(\mathbf{b}) \in \beta$ for all $\mathbf{b} \in B \cup \beta$. Therefore, if $f(\mathbf{a}) = 1$ and $f(\mathbf{b}) = 0$, then $\varphi(\mathbf{a}) \in \alpha$ and $\varphi(\mathbf{b}) \in \beta$, and this implies that $\varphi(\mathbf{a}) \not\leq \varphi(\mathbf{b})$, hence (10) holds.

This proves that the Quasi-polynomial Interpolation Problem for $n = 4$ and $L = \{0, 1\}$ can be reduced in polynomial time to $\mathbf{P}(\alpha)$, showing that the former is also NP-complete. \square

Summarizing Theorems 10 and 11, we obtain the following dichotomy result.

Corollary 12. *If $n \leq 3$ then the problem of deciding the existence of an interpolating quasi-polynomial function is in P, whereas for $n \geq 4$ it is NP-complete.*

6. CONCLUDING REMARKS AND FUTURE WORK

In this paper we considered the problem of interpolating empirical data given as couples consisting of a tuple specified by several attributes, together with its evaluation in a distributive lattice. The interpolating objects are lattice-valued functions, called quasi- and pseudo-polynomial functions, that can be factorized into a composition of a lattice polynomial function with possibly different local utility functions that evaluate each attribute in a distributive lattice. We presented necessary and sufficient conditions for the existence of quasi- and pseudo-polynomial functions interpolating a given finite set of examples. In doing so, we actually presented explicit descriptions of such solutions when they exist. Looking into complexity issues in computing them, we established a dichotomy result stating that, up to 3 attributes, the existence of an interpolating quasi-polynomial function can be decided in polynomial time, whereas this problem for sets of examples over more than 3 attributes becomes NP-complete. The analogous complexity question for pseudo-polynomial functions remains open.

Now our framework was motivated by problems typically arising in the qualitative approach to multicriteria decision making. The basic aggregation functions

considered, namely, lattice polynomial functions (that include Sugeno integrals), have neat representations, e.g., by disjunctive normal forms, and played a key role in the constructions provided. Other noteworthy aggregation functions in decision making, such as Lovász extensions (that include Choquet integrals), also share similar representation features. The natural step is to make use them when considering analogous interpolation problems for these aggregation models.

Furthermore, simplified notions of Sugeno and Choquet integrals (parametrized versions arising from the notions of k -maxitivity and k -additivity; see [16] for a general reference) have been proposed in the literature and could provide alternatives to avoid intractable complexity classes when dealing with interpolation problems.

These constitute few topics of our current interest, and that will be tackled in forthcoming research work.
